

Liftoff X — Operator Economics

The numbers behind "a better revenue model for the operator." Everything here is a model with explicit, adjustable assumptions — treat the assumptions as the things you validate in operator/aggregator calls, not as facts. Replace them with real figures as you learn them.

1. How the money works (crash game)

Turnover (total wagered)
└ $\times$ house edge (1 - RTP) $\rightarrow$ GGR (Gross Gaming Revenue = operator's gross win)
└ provider share (our revenue) = rev-share % $\times$ GGR
└ aggregator cut (if via aggregator)
└ operator keeps the rest (before their own costs: payments, platform, bonuses, marketing, tax)

- **GGR is the pie.** Both we and the operator are paid out of GGR.
- Lower RTP $\rightarrow$ bigger GGR (bigger pie) but worse for the player $\rightarrow$ tune per market.
- Our job: take a fair slice **and** grow the pie via retention (more rounds played).

2. Base assumptions (adjustable — validate these!)

Assumption	Base case	Notes
Avg stake per round	€1.00	crash bets are small; dual-bet lifts effective stake
Rounds wagered / active player / month	1,200	engaged players; our 2-bet design $\uparrow$ this
$\Rightarrow$ Turnover / active player / month	€1,200	= stake $\times$ rounds
RTP versions	97% / 96% / 95%	= 3% / 4% / 5% house edge
Aggregator cut (of our share)	0-25%	direct = 0%; via aggregator $\approx$ 20-25%

Change one number, everything below scales linearly. Keep this table as the single source of truth.

3. GGR per 1,000 active players / month

Turnover per 1,000 players = $1,000 \times €1,200 = \text{€1,200,000 / month}$.

RTP	House edge	GGR per 1,000 players / mo
97%	3%	€36,000
96%	4%	€48,000
95%	5%	€60,000

We'll use **RTP 96% (€48,000 GGR / 1,000 players)** as the running example below.

4. Rev-share scenarios — side by side

Three models to **test in conversations**. All shown at RTP 96%, per 1,000 active players/month (GGR = €48,000). "Operator keeps" is **before** the operator's own costs and any aggregator cut.

Model	Provider rate	Our revenue /1k/mo	Operator keeps /1k/mo
A — Operator-first (flat)	8%	€3,840	€44,160
B — Standard (tiered, ~11% eff.)	~11%	€5,280	€42,720
C — Premium (flat, incumbent-like)	15%	€7,200	€40,800

Tiered staffel (Model B) — per operator, by monthly GGR our game generates

Rewards bigger operators with a lower marginal rate (your "better at scale" hook):

GGR tier / month	Provider rate
First €50,000	14%
€50,000 – €250,000	10%
€250,000+	7%

5. The "better for the operator" headline

Versus an incumbent **15% / fixed-RTP** deal, at the **same** player base:

Per 1,000 active players/mo	Incumbent (15%)	Liftoff X (Model A, 8%)	Operator gain
Operator keeps (RTP 96%)	€40,800	€44,160	+€3,360 / mo
Annualised	€489,600	€529,920	+€40,320 / yr

Plus the **second lever**: our social/retention layer aims to lift rounds per player (the 1,200 assumption). Even at the same rev-share, +10% rounds = +10% GGR = more money for the operator **and** us. This is the real pitch: we grow the pie, not just split it cheaper.

6. Scaling — our revenue (RTP 96%)

Active players / mo	Model A (8%)	Model B (~11%)	Model C (15%)
1,000	€3,840/mo	€5,280/mo	€7,200/mo
10,000	€38,400/mo	€52,800/mo	€72,000/mo
100,000	€384,000/mo	€528,000/mo	€720,000/mo

7. Portfolio view (the venture-scale headline)

Distribution is via aggregators reaching ~5,000 operators — but **only a fraction go live, with very different player bases**. A deliberately conservative roll-up:

Assumption	Value
Operators live	150
Avg active players / operator	1,500
⇒ Total active players	225,000
GGR (RTP 96%, €48/player)	€10.8M / month
Our revenue @ 8% (Model A)	€864k / mo → €10.4M / yr
Our revenue @ 11% (Model B)	€1.19M / mo → €14.3M / yr

Net of a 20–25% aggregator cut on our share, knock ~⅓ off our revenue. Still a high-eight-figure ARR path if the live-operator and active-player assumptions hold — which is exactly what slides 4 & 8 of the deck must convince people of, and what the operator calls must validate.

8. What to validate in operator / aggregator calls

- **Avg stake & rounds/player** in real money (replaces the €1 / 1,200 guesses).
 - **Market-standard rev-share** for crash content (is 8-15% the right band?).
 - **Aggregator cut** — % of our share, or markup to the operator?
 - **Required RTP versions** per target market.
 - **Required certs & wallet API** (GLI vs iTech; seamless wallet flavour).
 - **Which markets** convert best for crash games (LatAm, India, Africa, EU...).
 - Appetite for **white-label** / **branded** versions (premium upsell).
-

9. Sensitivity cheatsheet

- Revenue scales **linearly** with: active players, stake, rounds, rev-share.
- Revenue scales with **house edge** ($1 - \text{RTP}$): 95% RTP vs 97% RTP = **+67%** GGR.
- The two highest-leverage levers you actually control: **(a)** getting live on more operators (distribution), **(b)** lifting rounds/player (retention) — which is precisely why the social layer is a commercial feature, not a nice-to-have.
